

## **Original Research Article**

### **The Effectiveness of the Heated Humidified High Flow Nasal Cannula as an Initial Noninvasive Respiratory Support for Preterm Infants Suffering from Respiratory Distress**

#### **ABSTRACT**

**Aims:** to compare the efficacy and safety of the heated humidified high-flow nasal cannula as a noninvasive respiratory support for the initial management of respiratory distress in preterm infants  $\geq 30$  weeks gestation with birth weight  $\geq 1300$  g at different flow rates (3 L/min and 6 L/min) on admission.

**Study design:** A Randomized controlled trial.

**Place and Duration of Study:**

Neonatal Intensive Care Unit, Pediatrics department, Tanta University Hospitals, over one-year period, from December 2018 to December 2019.

**Methodology:** 30 preterm neonates, with gestational ages ranged between 30 to 36 weeks and birth weight  $\geq 1300$  g, were randomized to receive HHHFNC at either flow rate 3 or 6 L/min as an initial respiratory support. Primary outcomes included: the incidence of treatment failure of the HHHFNC at flow 3 L/min and 6 L/min, which will require n CPAP or NIMV, or will require intubation. Secondary outcomes included: rate of deaths at any time after randomization, the total duration of all types of oxygen support and incidence of neonatal morbidities such as nasal trauma, symptomatic patent ductus arteriosus (PDA), intraventricular hemorrhage (IVH  $\geq$  grade II), pneumothorax, pulmonary hemorrhage, retinopathy of prematurity (ROP), apnea, sepsis and necrotizing enterocolitis (NEC  $\geq$  stage II).

**Results:** the incidence of the need for higher flow rate of HHHFNC (n=11, 36.6%) , the need for n CPAP or NIMV after failure of higher flow rate of HHHFNC (n=11, 36.6%), the need for intubation & MV (n=1, 3.3%), the incidence of nasal trauma (n=7, 23.3%), BPD (n=0) , IVH  $\geq$  II (n=0), NEC  $\geq$  II (n=0), pneumothorax (n=0) , the median duration of hospitalization =10 days (7-15), the median duration of all oxygen support = 6.5 days (6-7). The failure rate was 11 out of 30 infants (36.6%), no deaths or pulmonary haemorrhage.

**Conclusion:** HHHFNC use shows similar rates of efficacy to other forms of noninvasive respiratory support in preterm infants with respiratory distress for initial respiratory support with lesser complications. There were better outcomes with higher gestational age and birth weight at either flow rates 3 or 6 L/min.

**Note:** Review paper may have different types of subsections.

**Keywords:** *Heated Humidified High Flow Nasal Cannula, Noninvasive, Initial support, Preterm, Respiratory distress.*

#### **1. INTRODUCTION**

Preterm is live born infant delivered before 37 weeks from the first day of the last menstrual period according to world health organization <sup>(1)</sup>.

Premature births are responsible for 70% of neonatal mortality, 36% of infant mortality and 25-50% of long-term neurological disabilities. In the last 20 years with the scientific and technological developments observed in the field of neonatology, the survival rate of premature infants has significantly increased <sup>(2)</sup>.

Preterm neonates can develop many complications such as respiratory distress syndrome (RDS), intra-ventricular hemorrhage (IVH), necrotizing entero-colitis (NEC), broncho-pulmonary dysplasia (BPD), neonatal sepsis, patent ductus arteriosus (PDA), retinopathy (ROP) and hyperbilirubinemia <sup>(3)</sup>.

Respiratory distress syndrome is considered the major reason for increased mortality and morbidity among infants. Neonatal respiratory distress syndrome occurs in infants whose lungs have not yet fully developed. It can also be due to genetic problems with lung development. Most cases of RDS occur in babies born before 37 weeks <sup>(4)</sup>.

Respiratory support is being achieved more frequently with nasal continuous positive airway pressure (n CPAP) and other less invasive approaches, such as the technique of intubation, surfactant, and extubation (INSURE) <sup>(5)</sup>.

The non-invasive respiratory support, including n CPAP, was shown to be effective in treating infants in the initial phase of respiratory distress. The heated humidified high-flow nasal cannula (HHHFNC) is frequently used as an alternative mode of noninvasive respiratory support in the neonatal intensive care unit. Because it has a simpler interface with the infant and smaller prongs than n CPAP, the cannula is perceived as easier to use, more comfortable for the infant, and advantageous for mother–infant bonding <sup>(6)</sup>.

Recent Cochrane review of HHHFNC use in preterm infants concluded that it is effective as other forms of non-invasive respiratory support in preterm infants for preventing treatment failure, death and chronic lung disease <sup>(7)</sup>.

The HHHFNC is not only used as a primary respiratory support but also used after extubation to prevent alveolar collapse. However, it also has some drawbacks such as nasal trauma, head deformity, gaseous bowel distension and the difficulty to maintain the device on infant's face at all time to obtain the constant pressure <sup>(8)</sup>.

The HHHFNC has been used as a respiratory support for various purposes including apnoea of prematurity <sup>(9)</sup>, primary respiratory support in respiratory distress syndrome <sup>(10)</sup>, CPAP weaning <sup>(11)</sup> and post extubation <sup>(12)</sup>.

Also, neonatal HFNC is increasingly being applied in other clinical areas including during neonatal transport and for initial delivery room stabilization of premature infants <sup>(13,14,15)</sup>.

## 2. MATERIAL AND METHODS / EXPERIMENTAL DETAILS / METHODOLOGY

We enrolled total 45 preterm neonates after delivery in this study (15 preterm infants were excluded due to major congenital malformations, or congenital heart disease), they were admitted in the Neonatal Intensive Care Unit (NICU), Pediatrics department, Tanta University Hospitals, over one-year period, from December 2018 to December 2019, after the approval from the ethical committee of Tanta University and after written parental consents before the enrollment.

This study was a randomized controlled trial. Simple randomization was performed by using computed generated random numbers. It was double blinded with fixed and standard protocols for initiation, weaning, extubation and identification of treatment failure.

- 30 included preterm neonates, with gestational age  $\geq 30$  weeks and less than 37 weeks, who were suffering from mild to moderate respiratory distress on admission, were randomized to receive HHHFNC (Fisher & Paykel Optiflow System, Healthcare, Auckland, New Zealand) as an initial respiratory support <sup>(16)</sup>.
- This group was sub classified into subgroup **A** started initially at flow rate **3 L/min.** and subgroup **B** started initially at flow rate **6 L/min.**

**Inclusion criteria**

- Preterm neonates, born of gestational age  $\geq 30$  weeks and of birth weight  $\geq 1300$  g, suffering from signs and symptoms of respiratory distress after delivery.

**Exclusion criteria**

- Preterm neonates of gestational age  $< 30$  weeks and of birth weight  $< 1300$  g.
- Preterm neonates with major congenital heart diseases, upper airway anomalies, lung hypoplasia and neuromuscular disorders.
- Full term neonates.
- Preterm infants who required intubation and mechanical ventilation after delivery.

**Usage of the HHHFNC:**

- All infants,  $\leq 34$  weeks were received IV caffeine citrate either a loading dose of 20 mg/kg/dose or a maintenance dose of 5 mg/kg/day in the first 24 hours.
- Infants were treated with HHHFNC (Fisher & Paykel Optiflow System, Healthcare, Auckland, New Zealand) <sup>(16)</sup>, with the orifice diameter of the nasal cannula (2.4 to 2.7 mm) and were fitted to maintain a leak at the nose as recommended by the user manual with the aim of occluding approximately half of the nares.
- Flow rates of HHHFNC were modified from 3 into 6 L/min or from 6 into 8 L/min. when needed.
- Oxygen saturation targets were maintained at 90-95% on HHHFNC, all infants stayed on this assigned mode of respiratory support until they were able to be managed without any respiratory support.

**Weaning from HHHFNC:**

Treatment with HHHFNC was stopped, as ordered by the treating team, when the infants showed no signs of respiratory distress with room air, weaned to flow rate 2 L/min. and SpO<sub>2</sub>  $> 90\%$ , PCO<sub>2</sub>  $< 50$  mmHg with FiO<sub>2</sub> of 0.21 <sup>(17)</sup>.

**HHHFNC treatment failure was indicated by one or more of the following:**

- I. Respiratory acidosis (PaCO<sub>2</sub>  $> 60$  mmHg with pH  $< 7.25$  at maximum setting of the allocated device [flow rate 7-8 L/min]), hypoxia (FiO<sub>2</sub>  $> 0.4$  to maintain SpO<sub>2</sub> 88 to 94%) <sup>(17)</sup>.
- II. Significant apnea ( $> 2-3$  episodes of apnea/hour requiring bag and-mask ventilation in 24 hour period or 6 or more apneic episodes requiring tactile stimulation within 6 hours) despite adequate prong fixation and flow <sup>(17)</sup>.
- III. Persistent marked/severe retractions.
- IV. Urgent need for ETT & MV as in cardiovascular collapse or shock as determined by the treating team.
  - When a neonate met one or more of the above criteria, increasing flow rate from 3 into 6 L/min. or from 6 into 8 L/min. was done, then application of other type of non-invasive respiratory support device (from HHHFNC to n CPAP and from n CPAP to NIMV) was considered within 6 hours approximately or required MV if indicated.

**The HHHFNC outcomes:****Primary outcomes:**

The incidence of treatment failure of the HHHFNC at flow 3 L/min and 6 L/min, which will require n CPAP or NIMV, or will require intubation.

**Secondary outcomes:**

1. Rate of deaths at any time after randomization.
2. The total duration of all types of oxygen support.
3. Incidence of neonatal morbidities such as nasal trauma, symptomatic patent ductus arteriosus (PDA), intraventricular hemorrhage (IVH  $\geq$  grade II), pneumothorax, pulmonary hemorrhage, retinopathy of prematurity (ROP), apnea, sepsis, and necrotizing enterocolitis (NEC  $\geq$  stage II).

**All preterm neonates were subjected to the followings:**

**A-** Complete history taking which included:

- Peri-natal history.
- Natal history of labor and delivery.
- Resuscitation history.

**B-** Full clinical examination.

**C-** Routine laboratory investigations.

**D-** Chest X-ray.

**E-** Transcranial US.

#### Statistics

Data were analyzed using SPSS 22. Chi-square and t test were used for quantitative and qualitative variables,  $P < 0.05$  was considered as significant level.

## 4. RESULTS

**Table 1: Demographic data of subgroup A & B (n=30) showing:**

- There was no significant difference between the two studied subgroups A & B as regard sex, gestational age, mode of delivery & age of start of HHHFNC.

#### 4-DISCUSSION

In this present study, in the main studied group (HHHFNC used as an initial respiratory support), as regard the demographic data, anthropometric measurements, antenatal risk factors and HHHFNC outcomes, there was no significant difference between both low and high flow rates subgroups A & B except for incidence of preeclampsia and eclampsia in B (n=8, 53.3%) was higher than in A (n=1, 6.7%).

We enrolled 30 preterm infants in with mean GA 33 weeks (32.5-34) & mean BW 2200 g (1800-2500).

Resulted in the followings : the incidence of the need for higher flow rate of HHHFNC (n=11, 36.6%) , the need for n CPAP or NIMV after failure of higher flow rate of HHHFNC (n=11, 36.6%), the need for intubation & MV (n=1, 3.3%), the incidence of nasal trauma (n=7, 23.3%), BPD (n=0) , IVH ≥ II (n=0), NEC ≥ II (n=0), pneumothorax (n=0) , the median duration of hospitalization =10 days (7-15), the median duration of all oxygen support = 6.5 days (6-7). The cases who needed for n CPAP or NIMV, were changed into higher flow rate first and the case who needed for intubation, was first put on n CPAP or NIMV so failure rate was 11 out of 30 infants (36.6%), no deaths or pulmonary haemorrhage.

This comes in comparison with **Shin, et al., 2017** <sup>(17)</sup>, who enrolled 42 preterm infants, were randomized to HHHFNC as a primary support when they showed respiratory distress in < 24 hours of age, using the Optiflow system as our study, at the same flow rates, the same weaning criteria from HFNC and the same criteria of treatment failure (intubation). Preterm infants who needed invasive respiratory supports were excluded unlike our study and, they compared the HFNC group to another n CPAP group. The HFNC group, with similar mean GA (32.5±1.5 weeks) and BW (2058±371 g), showed higher failure rate (16%), less need for n CPAP or NIMV (3%), more need for intubation (13%), higher incidence of BPD (n=1, 2.3%), higher incidence of air leak (n=2, 4.7%), IVH ≥ III (n=0), NEC ≥ II (n=0), longer mean duration of hospitalization =20 days (15.8-28.3) and longer mean

duration of all oxygen support =67 days (40-106.8). These differences may be due to the different clinical decisions and rescue treatment.

While in comparison with **Sharma, et al., 2019** <sup>(18)</sup>, who enrolled 50 preterm infants with mild to moderate respiratory distress were randomized to HHHFNC as a primary respiratory support within the first 6 h of birth, with smaller mean GA ( $31.77 \pm 2.21$  weeks) and BW ( $1762 \pm 493.5$  g), showed higher failure rate 6 out of 50 infants (12%) who needed for intubation and MV, less incidence of nasal trauma (11.4%) and shorter mean duration of total oxygen supplementation =3.48 days. Their study differed from ours in the used devices, the flow rates, the primary outcomes, the weaning protocol, and the rescue treatment.

**Dimirel, et al., 2019** <sup>(19)</sup>, who used the HFNC as a first line respiratory support for preterm infants who had spontaneous respiration after admission initially at flow rate 6 L/min and increasing maximally into 8 L/min. They followed the same weaning protocol from HFNC and the same extubation criteria. They enrolled 53 preterm infants with smaller mean GA ( $31.2 \pm 2.3$  weeks) and BW ( $1570 \pm 455$  g). They found higher intubation (treatment failure) rate ( $n=5$ , 9.4%), higher incidence of BPD ( $n=4$ , 7.5%), IVH  $\geq$  II ( $n=2$ , 3.7%), NEC  $\geq$  II ( $n=1$ , 1.8%), pneumothorax ( $n=2$ , 3.7%), longer median duration of hospitalization =27 days and shorter median duration of all oxygen support = 3 days. They differed from us in the used Vapotherm system and the clinical decisions.

**Murki, et al., 2018** <sup>(20)</sup>, who enrolled 133 preterm infants with respiratory distress using HFNC as a primary respiratory support with initial flow rate 5 L/min and increased gradually to the maximal flow rate 7 L/min, with smaller mean GA  $31.8 \pm 1.9$  weeks and BW  $1632 \pm 431$ g. They used the same Optiflow system, followed the same treatment failure criteria and the same outcomes. They found lower treatment failure rate within 72 h ( $n= 35$ , 26.3%), shorter duration of oxygen support ( $6.7 \pm 4.125$  days), higher incidence of nasal trauma ( $n=7$ , 5.3%), pneumothorax ( $n=0$ ), IVH  $\geq$  III ( $n=0$ ), higher incidence of NEC  $\geq$  II ( $n=2$ , 1.5%), longer duration of hospitalization ( $18 \pm 13$  days) and higher death rate ( $n=4$ , 3%). Their study differed in the larger numbers included with wider range of GA and BW and also in the clinical rescue decisions.

**Manley, et al., 2018** <sup>(21)</sup>, undertook the HIPSTER trial, an international, multicenter, randomized, noninferiority trial in preterm infants born at 28-36 weeks of gestation that used HFNC 6-8 L/min as primary respiratory support for early respiratory distress. All 278 infants in the HFNC group of HIPSTER were included. The mean GA and BW were ( $32.0 \pm 2.1$  weeks) and ( $1737 \pm 580$  g), and 140 infants (50.4%) were born at < 32 weeks. Caffeine was administered to 109 infants (39.2%) in the first 24 hours of life. The primary outcome was treatment failure within 72 hours after randomization. 71 infants (25.5%) had treatment failure of lower rate compared to our study. In that

analysis, when the 30/30 rule was applied: 'infants with both a GA of  $\geq 30$  weeks and an early ( $< 2$  hours of age)  $\text{FiO}_2 < 0.30$  are more likely to be successfully treated with HFNC and avoid intubation than infants born  $< 30$  weeks of gestation or with an early  $\text{FiO}_2 \geq 0.30$ , or both', about 84% of infants were successfully treated, about 16% required CPAP "rescue," and 7% were intubated. The differences might be due to the larger numbers included with wider range of GA and smaller BW, the used devices and the different NICUs' protocols.

**Zheng, et al., 2017** <sup>(22)</sup>, who enrolled 65 preterm infants, with mild to moderate RDS requiring initial noninvasive respiratory support; were applied to the HHHFNC, with smaller GA ( $31.9 \pm 1.7$  weeks), BW ( $1754 \pm 299$  g). They used the Optiflow and the Vapotherm systems at flow rates 6-8 L/min. They followed the same intubation criteria. Their results showed higher need for intubation (treatment failure) within 7 days ( $n=13$ , 20%) unlike ours, higher incidence of BPD ( $n=6$ , 9.2%), higher incidence of IVH  $\geq \text{III}$  ( $n=3$ , 4.6%), same incidence of nasal trauma ( $n=14$ , 21.5%), air leak ( $n=2$ , 3.1%), longer mean duration of hospitalization = 30.5 days (14-55) and death rate ( $n=1$ , 1.5%). These differences due to the different observational cross-sectional study, used devices, flow rates, protocols, defined primary outcome and decisions.

**Lavizzari, et al. 2016** <sup>(23)</sup>, who enrolled 158 preterm infants with mild to moderate RDS, were randomly applied to the HHHFNC as a primary support, with mean GA ( $33.1 \pm 1.9$  weeks), BW ( $1968 \pm 581$  g). They used the Vapotherm system at flow rates 4-6 L/min, followed the same extubation criteria but different intubation indication and weaning criteria from the HHHFNC. Their results showed higher incidence of need for MV within 72 h ( $n=17$ , 10.8%), higher incidence of BPD ( $n=7$ , 4.4%), higher incidence of IVH  $\geq \text{III}$  ( $n=6$ , 3.8%), higher incidence of air leak ( $n=3$ , 1.9%), higher incidence of NEC  $\geq \text{II}$  ( $n=1$ , 0.6%), mean duration of total oxygen support = 7.5 days, longer mean duration of hospitalization = 20 days (11-35).

**Kugelman, et al., 2015** <sup>(10)</sup>, who enrolled 38 preterm infants, randomized to HHHFNC (1 – 5 L/min.) as a primary support, with mean GA 32.5 (27.5-34.7 weeks) and mean BW ( $1759 \pm 488$  g), showed incidence of need for higher flow rate from 3 L/min. ( $n=14$ , 36.8%), higher incidence of need for MV ( $n=11$ , 28.9%), higher incidence of BPD ( $n=1$ , 2.6%), higher incidence of IVH  $\geq \text{III}$  ( $n=1$ , 2.6%), nasal trauma ( $n=0$ ), air leak ( $n=0$ ), NEC  $\geq \text{II}$  ( $n=0$ ), death ( $n=0$ ) and longer mean duration of hospitalization = 39.5 days (9-113). They differed from us in the pilot study, used Vapotherm at different flow rates and protocols of weaning and intubation.

Lastly, **Fleeman, et al., 2019** <sup>(24)</sup>, updated a systematic review and meta-analyses examining the efficacy and safety of HHHFNC compared with standard treatments for preterm infants. The analysis of primary respiratory support included ten RCTs ( $n = 1,676$ ). They found higher intubation rate ( $n$

=90\704, 12.8%) compared to our study, higher incidence of BPD (n =27\348, 7.8%), death rate (n =5\717, 0.7%), air leak (n =15\702, 2.1%) and nasal trauma (n =42\578, 7.3%). All the differences are mostly due to the different used devices, flow rates, outcomes, NICUs' protocols, larger ranges of numbers included, GA and BW and the pragmatic clinical decisions.

In this present study, there was a significant positive relation between gestational age and success rate of HHHFNC as initial support at flow rate 3 l/min. as showed in subgroup A with higher number of cases who were not needed for n CPAP or NIMV after failure of higher flow of HHHFNC.

There was a significant positive relation between gestational age and success rate of HHHFNC as initial support at flow rate 6 l/min. as showed in subgroup B with higher number of cases who were not needed for n CPAP or NIMV after failure of higher flow of HHHFNC.

This comes in comparison to, **Lavizzari, et al. 2016** <sup>(23)</sup>, who enrolled 158 preterm infants with mild to moderate RDS, were randomly applied to the HHHFNC as a primary support. They found that there was no difference in respiratory failure rate in any GA stratum.

While in comparison with, **Zheng, et al., 2017** <sup>(22)</sup>, who enrolled 65 preterm infants, with mild to moderate RDS requiring initial noninvasive respiratory support; were applied to the HHHFNC. They found that there were no significant differences in neonates older than 28 weeks of gestational age in the primary outcome: treatment failure within the first 7 days.

While **Murki, et al., 2018** <sup>(20)</sup>, who enrolled 133 preterm infants with respiratory distress using HFNC as a primary respiratory support. They found that the risk difference of treatment failure was higher among infants with lower gestation (<32 weeks: 14.7%, ≥32 weeks: 10.1%).

In this present study, there was a significant positive relation between birth weight and not needing for higher flow rate of HHHFNC as showed in subgroup A at flow rate 3 l/min.

There was a significant positive relation between birth weight and success rate of HHHFNC as initial support at flow rate 3 l/min. as showed in subgroup A with higher number of cases who were not needed for n CPAP or NIMV after failure of higher flow of HHHFNC.

There was a significant positive relation between birth weight and success rate of HHHFNC as initial support at flow rate 6 l/min. as showed in subgroup B with higher number of cases who were not needed for higher flow rate of HHHFNC and not needed for n CPAP or NIMV after failure of higher flow of HHHFNC.

There was no significant relation between birth weight and need for intubation as HHHFNC outcome in the main studied group(Initial support).

This comes in agreement with, **Yoder, et al., 2013** <sup>(25)</sup>, who enrolled 212 infants, who were randomly assigned to HHHFNC (at flow rates 2 to 8 L/min.) as a primary support, with mean GA ( $33.5 \pm 3.6$  weeks) and BW ( $2201 \pm 816$  g). They found that the adjustment for gestation, birth weight, ventilator support, surfactant therapy, and primary diagnosis did not alter the failure rates to identify a significant difference between the study modes for early intubation.

**5. CONCLUSION:** our study concluded that:

- HHHFNC use has similar rates of efficacy to other forms of non-invasive respiratory support in preterm infants with respiratory distress for initial respiratory support.
- HHHFNC showed lesser complications on either flow rates 3 or 6 L/min. as regard nasal trauma, pneumothorax, pulmonary hemorrhage, IVH  $\geq$  ii, NEC  $\geq$  ii, PDA and death.
- There were better outcomes for the use of HHHFNC with higher gestational age and birth weight as an initial respiratory support at either flow rates 3 or 6 L/min.

**CONSENT (WHEREVER APPLICABLE)**

No manuscripts will be peer-reviewed if a statement of patient consent is not presented during submission (wherever applicable).

This section is compulsory for medical journals. Other journals may require this section if found suitable. It should provide a statement to confirm that the patient has given their informed consent for the case report to be published. Journal editorial office may ask the copies of the consent documentation at any time.

Authors may use a form from their own institution or SDI Patient Consent Form 1.0. It is preferable that authors should send this form along with the submission. But if already not sent during submission, we may request to see a copy at any stages of pre and post publication.

If the person described in the case report has died, then consent for publication must be collected from their next of kin. If the individual described in the case report is a minor, or unable to provide consent, then consent must be sought from their parents or legal guardians.

Authors may use the following wordings for this section: "All authors declare that 'written informed consent was obtained from the patient (or other approved parties) for publication of this case report and accompanying images. A copy of the written consent is available for review by the Editorial office/Chief Editor/Editorial Board members of this journal.'"

**ETHICAL APPROVAL (WHEREVER APPLICABLE)**

This section is compulsory for medical journals. Other journals may require this section if found suitable. If human subjects are involved, informed consent, protection of privacy, and other human rights are further criteria against which the manuscript will be judged. It should provide a statement to confirm that the authors have obtained all necessary ethical approval from suitable Institutional or State or National or International Committee. This confirms

either that this study is not against the public interest, or that the release of information is allowed by legislation.

All manuscripts which deal with animal subjects must be approved by an Institutional Review Board (IRB), Ethical Committee, or an Animal Utilization Study Committee. , and this statement, and approval number, must accompany the submission. If required, author should be ready to submit a scanned copy of the IRB or Ethical Committee Approval at any stage of publication (Pre of post publication stage). The manuscript should contain information about any post-operative care and pain management for the animals.

For manuscripts involving animal experiments, Authors may use the following wordings for this section "All authors hereby declare that "Principles of laboratory animal care" (NIH publication No. 85-23, revised 1985) were followed, as well as specific national laws where applicable. All experiments have been examined and approved by the appropriate ethics committee"

All manuscripts which deal with the study of human subjects must be accompanied by Institutional Review Board (IRB) or Ethical Committee Approval, or the national or regional equivalent. The name of the Board or Committee giving approval and the study number assigned must accompany the submission. If required, author should be ready to submit a scanned copy of the IRB or Ethical Committee Approval at any stage of publication (Pre of post publication stage).

For manuscripts involving human experiments, Authors may use the following wordings for this section: "All authors hereby declare that all experiments have been examined and approved by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in the 1964 Declaration of Helsinki."
