28

This work evaluates the radiation hazard indices from some selected mining sites in Nasarawa 10 West, using Sodium Iodide Thallium Gamma Spectrometry. Raeq ranged from 100.39-11 12 197.40Bq/Kg with a mean 161.44Bq/Kg, which is lower than the average of 370Bq/Kg. The GADR ranged from 44.85nGy/hr-90.71nGy/hr with the mean 73.68nGy/hr. which is also below 13 the average of 89 nGy/hr for soil. The AGED ranged from 315.77 - 640.91 mSv/yr with the 14 15 mean 519.19 mSv/yr. Which is above the threshold value of 300 mSv/yr. ACI ranged from 0.73-16 1.45 with the mean value 1.18 which is above the standard of unity. The AEDE (outdoor) ranges from 0.055 - 0.111 mSv/yr with the mean 0.090mSv/yr which is above the 0.07mSv/yr 17 standard permissible limit. The AEDE (indoor) ranged from 0.220 - 0.445mSv/yr, with the mean 18 value 0.361mSv/yr, a value below the 0.45mSv/yr threshold. The ELCR ranged from 00.770-19 1.558 with the mean value 1.265 and from 0.193 - 0.389 with the mean value 0.317 for outdoor 20 and indoor respectively, which exceed the 0.29 X 10⁻³ threshold limit. The External and Internal 21 Hazard indices ranges from 0.271 - 0.533 and 0.289 - 0.675 as well as mean values 0.435 and 22 0.512 respectively, which are below the threshold. Therefore, there may be serious radiological 23 effects to the populace. 24

Keywords: Radionuclide, Radiation, Hazard Indices, Excess Lifetime Cancer Risk,
 Nasarawa State.

29 1. INTRODUCTION

The measurement of natural radioactivity in our environment allows the determination and 30 assessment of population exposure to radiation. The occurrence of natural radionuclides in water 31 32 depends on the waters origin as well human activities in the area, such as the geology of the area, 33 tin mining and use of fertilizers in agriculture [4]. For groundwater (boreholes and wells), it depends on their presence and contents in lithological of solids aquifers or rocks known as 34 35 geological materials particularly the Jos Plateau rock types amounts of radioactive elements such as Uranium, thorium and potassium which may dissolve into ground water system during 36 water/rock -soils interaction mechanism [5].Consumption of ground water with elevated 37 38 amounts of natural radionuclides may increase the radio-toxicity to human and internal exposure to radiation caused by the decay of the natural radionuclides taken into the body through 39 ingestion as well as inhalation. The decay process leads to the release of several alpha and beta 40 particles which are responsible for the total radiation dose received from natural radioactivity as 41 well as artificial [3]. The aim of this study was to Evaluation of Radiation Hazard Indices and 42 Excess Lifetime Cancer Risk in Mining Sites of Nasarawa State. Nigeria. 43

Comment [O1]: Repetitions could be limited by rewtiring as:

This work evaluates the radiation hazard indices from some selected mining sites in Nasarawa West, using Sodium Iodide Thallium Gamma Spectrometry. Ra_{eq} ranged from 100.39 - 197.40 Bq/Kg with a mean of 161.44 Bq/Kg while the GADR ranged from 44.85 - 90.71 nGy/hr with a mean of 73.68 nGy/hr respectively. The Ra_{eq} and GADR were lower than the recommended values of 370Bq/Kg and 89 nGy/hr for soil.

Comment [O2]: The AGED ranged from 315.77 - 640.91 mSv/yr with the mean 519.19 mSv/yr, a value above the threshold value of 300 mSv/yr.

Comment [O3]: Therefore, the values reported indicated a possible serious radiological effects to the populace within the studied area.

47 48

49 2. MATERIALS AND METHODS

50 **2.1 Materials**

- 51 In the course of the radiometric study, the following items or materials were used as shown in
- 52 Table 1.

Materials	Specifications
Inspector Alert Nuclear Radiation Monitor	This is a health and safety instrument that is optimized to detect the physical levels of activity concentration of the radionuclides present in the environment.
Global Positioning System (G.P.S)	This is a space-based satellite navigation system that provides location and time information in all weather, anywhere or near the earth. This was used to locate the mining sites.
Disposable Hand Glove	This is a shielding material used to protect the hands and fingers from contacting any radioactive source.
Measuring Tape	This was used to measure the depth of the pit and also to measure the distance between two points.
Masking Adhesive Tape	This was used to label the samples for easier identification.
Marker pen	This was used to mark the masking tape attached to the polythene bag for easy
	identification of the soil samples.
Polythene Bags	To avoid mixing up of the samples, each of the collected samples were parked into a labeled polythene bag.
Sacks	The labeled polythene bags containing the collected samples were parked
	together into a single sack for easy transportation.
Mortar and Pestle	This was used to ground the collected samples after being dried at 60° C to 80° C
	for 24 hours in order to maintain the radioactive equilibrium.
5mm-Mesh Sieve	This was used to sieve the grounded samples in order to remove any larger
	particles in it and make it a powder.
Cylindrical Plastic Container	The sieved powder was packed into a cylindrical plastic container and the cover will be sealed with a masking tape to prevent it from any external radiation.
Electronic Analytical Balance	The sealed containers were placed on the electronic analytical balance to
	measure its weight in grams.
0.4	
Cutlass	This was used for clearing of the mining sites also for shallow digging.
Coolor	This was used to east the signed and laboled complex in their respective.
Sealer	container in order to avoid leakage also to prevent the escape of gaseous ²²² Rn from the sample.
Sodium Jodido Thalium Commo	This is an instrument set in the laboratory, which was used to engly a the soil
Spectroscopic System	samples.

- 53
- 54 2.1 Study Area
- 55 Four villages were chosen in Mararraba-Udege Area. The villages are Eyenu, OPanda, Okereku
- and Udegen-Mbeki abbreviated as NW1, NW2, NW3 and NW4 respectively. The villages NW1,
- 57 NW2, NW3 and NW4 are located at 08°24'38.2"N and 007°52'59.2"E, 08°21'24.9"N and

58 $007^{0}54^{2}9.6^{\circ}E$, $08^{0}24^{\prime}04.1^{\circ}N$ and $007^{0}52^{\prime}10.6^{\circ}E$ and $08^{0}25^{\prime}56.3^{\circ}N$ and $007^{0}53^{\prime}49.3^{\circ}E$ respectively. 59 Columbite was mined in all the four villages as represented in Figure 1:

60

63

61 Fig: 1. Map of Study Area

62 2.2 Sampling and Analysis

2.2.1 Samples Collection

64 Four sample locations were visited from all over Nasarawa West, Nigeria, to conduct the 65 radiometry study. Three samples will be collected from each sample area to make twelve samples of soil. The samples were collected at 0.5m depth level from the surface of the soil. 66 From each area, as stated earlier, three samples were collected as follows. Firstly from the 67 68 mining spot, secondly from a distance of 100m away from the mining spot, and thirdly, from the 69 river area within the mining spot. The collected samples were sealed in a labeled polythene bags 70 and enclose into one sack for easiest transportation from the mining or sample point to the house. 71 Meanwhile, when collecting the sample from the mining spot, Inspector Alert Nuclear Radiation 72 Monitor was set at one meter above the ground to measure the physical activity concentration of 73 the radionuclides present in the soil. In addition, Global Positioning System (GPS) was used to 74 take the elevation and altitude of the area, and thermometer to measure the atmospheric temperature of the mining spot. 75

76 2.2.2 Sample Preparation Techniques

The collected samples (soil or sediment) was brought into the laboratory to be left open (if wet) for a minimum of 24 hours to dry under ambient temperature. They will be grounded using mortar and pestle and allowed to pass through 5mm-mesh sieve to remove larger object and make it fine powder. The samples will be packed to fill a cylindrical plastic container of height 7cm by 6cm diameter. This satisfied the selected optimal sample container height. Each container will accommodate approximately 300g of sample. They will be carefully sealed (using

Comment [05]: Be specific, were the samples wet? Thus left for minimum of 24 hours?

Comment [O4]: A better image maybe required

for clarity sake

- 83 Vaseline, candle wax and masking tape) to prevent radon escape and then stored for a minimum
- of 24 days. This is to allow radium attain equilibrium with the daughters.

85 2.2.3 Sample Analysis

Gamma-ray spectrometry technique was employed in the spectral collection of the preparedsample using the higher energy region of the gamma-lines.

88 2.3 Data Analysis

The principal primordial radionuclides that would be discuss for all the radiological parameters (Radium Equivalent Activity Ra_{eq} , Absorbed Dose Rate, Effective Dose Rate, External Hazard

91 Index $H_{(ex)}$ and Internal Hazard Index $H_{(in)}$) in this case are ²²⁶Ra, ²³²Th and ⁴⁰K.

92 2.3.1 Radium Equivalent Activity (Ra_{eq})

93 This first index can be calculated using[2] relation:

94 $Ra_{eq} = A_{Ra} + 1.43A_{Th} + 0.077A_{K}$

- Where A_{Ra} , A_{Th} and A_{K} are the specific activities of ²²⁶Ra, ²³²Th and ⁴⁰K in Bq/kg, respectively.
- The Ra_{eq} is related to the external Γ -dose and internal dose due to radon and its daughters. The values must be less than 370Bq/kg, for the area to be acceptable to the public

98 2.3.2 Absorbed Dose Rate

- 99 According to [7], conversion factors to transform specific activities A_{Ra} , A_{Th} and A_K of ²²⁶Ra, 100 232 Th and 40 K, respectively, in absorbed dose rate at 1meter above the ground (in nGy/hr by
- 101 Bq/kg) are calculated by Monte Caro method as:

102 $D(nGy/hr) = 0.0417A_K + 0.462A_{Ra} + 0.604A_{Th}$ (2)

Where A_{Ra} , A_{Th} and A_{K} are the activities of ²²⁶Ra, ²³²Th and ⁴⁰K in Bq/kg, respectively.

104 The world average value for the Absorbed Dose Rate is 89nGy/hr for public.

105 2.3.3 Annual Gonadal Equivalent Dose (AGED)

106 An increase in AGED has been known to affect the bone marrow and destroys the red

- blood cells which are then replaced by white blood cells. This situation results in a blood
 cancer (leukemia). According to [1], AGED is calculated with given activity concentration of
- 109 226 Ra, 232 Th and 40 K (in Bq/Kg) using the relation: 110 AGED (mSv/yr) = $3.09A_{Ra} + 4.18A_{Th} + 0.314A_{K}$

$$ED (mSv/yr) = 3.09A_{Ra} + 4.18A_{Th} + 0.314A_{K}$$
(3)

Where, A_{Ra} , A_{Th} , and A_{K} are the radioactivity concentration of ²²⁶Ra, ²³²Th and ⁴⁰K (in Bq/Kg) in soil samples respectively.

113 2.3.4 Activity Concentration Index (Representative Gamma Index).

114 According to [1], the activity concentration index is given by:

115 $I_{\gamma_{T}} = \frac{Ara}{150} + \frac{Ath}{100} + \frac{Ak}{1500}$

(4)

(1)

- Where, A_{Ra} , A_{Th} , and A_K are the radioactivity concentration of ²²⁶Ra, ²³²Th and ⁴⁰K (in Bq/Kg) in soil samples respectively.
- 118 An increase in the representative gamma index greater than the universal standard of unity may
- 119 result in radiation risk leading to the deformation of human cells thereby causing cancer. Values
- 120 of $I_{\gamma_r} \le 1$ corresponds to an annual effective dose of less than or equal to 1 mSv, while $I_{\gamma_r} \le 0.5$
- 121 corresponds to annual effective dose less or equal to 0.3 mSv.

122 2.3.5 Annual Effective Dose Equivalent (AEDE)

- 123 The annual effective dose equivalent received outdoor by a person is calculated from the
- absorbed dose rate by applying dose conversion factor of 0.7 Sv/Gy. Taking into consideration
- that people on average, spent 20% of their time outdoors, occupancy factor for outdoor and indoor is 0.2 (5/24) and 0.8 (19/24) respectively [8], [9].
- 127 According to [8] & [9], AEDE is determined by the equations below.
- 128 AEDE (Outdoor) (mSv/y) = D (nGy/ h) × 8760h × 0.7 Sv/Gy× 0.2×10^{-6} (5)

129 And

- AEDE (Indoor) (mSv/y) = D (nGy/h) \times 8760h \times 0.7 Sv/Gy \times 0.8 \times 10⁻⁶ 130
- The AEDE (indoor) occurs within a house whereby the radiation risks due to building 131 materials only are taken into consideration while AEDE (outdoor) involves a consideration of 132
- the absorbed dose emitted from radionuclides in the environment such as ²²⁶Ra, ²³²Th and 133
- ⁴⁰K. The standard AEDE (Outdoor) value is 0.07 mSvyr⁻¹ and that for AEDE (Indoor) is 0.45 134 mSvyr⁻¹. These indices measure the risk of stochastic and deterministic effects in the irradiated 135
- 136 individuals.

137 2.3.6 Excess Lifetime Cancer Risk (ELCR)

- An increase in the ELCR causes a proportionate increase in the rate at which an individual can 138 get cancer of the breast, prostate or even blood. According to [6], Excess lifetime cancer risk 139
- 140 (ELCR) is given by; $ELCR = AEDE \times DL \times RF$ 141

(7)

(6)

- Where AEDE is the Annual Effective Dose Equivalent, DL is the average duration of life 142
- / life expectancy (estimated as 70 years), and RF is the Risk Factor (Sv⁻¹), i.e. fatal cancer risk 143
- per Sievert. For stochastic effects, International Commission on Radiological Protection (ICRP) 144 uses RF as 0.05 Sv^{-1} for public with the ELCR UNSCEAR standard being 0.29×10^{-3} .
- 145

2.3.4 External Hazard Index 146

This hazard denoted in terms of External Hazard Index or outdoor radiation hazard index and 147 denoted by H_{ex}, according to [2], can be calculated using the equation: 148

149
$$H_{ex} = \frac{Ara}{370} + \frac{Ath}{259} + \frac{Ak}{4810} \le 1$$
 (8)

- Where A_{ra} , A_{th} and A_k are activity concentrations of ²²⁶Ra, ²³²Th and ⁴⁰K in Bq/kg respectively. 150
- The value of the internal hazard index must be less or equal to unity in order for the radiation 151 hazard to be negligibly hazardous to the respiratory organs of the public.
- 152

2.3.5 Internal Hazard Index 153

- The Internal hazard Index (Hin) gives the internal exposure to carcinogenic radon and according 154 to [2], is given by the formula 155
- $H_{in} = \frac{Ara}{185} + \frac{Ath}{259} + \frac{Ak}{4810} \le 1$ 156

(9)

- Where A_{ra} , A_{th} and A_k are activity concentrations of ²²⁶Ra, ²³²Th and ⁴⁰K in Bq/kg respectively. 157 The value of the internal hazard index must be less or equal to unity in order for the radiation 158
- hazard to be negligibly hazardous to the respiratory organs of the public [2]. 159

160 3. RESULT

3.1 Result 161

This shows the experimental results obtained from the spectra of twelve soil samples under 162

investigation. For the effective computation of the experimental data from Count Dose Rate 163 (cpm) to Exposure Dose Rate (µSvhr⁻¹), Absorbed Dose Rate (nGyhr⁻¹), Annual Effective Dose 164

Rate (mSvyr⁻¹), Annual Gonadal Equivalent Dose Rate (mSv/yr), Activity Concentration Index 165

(representative gamma index), Excess Lifetime Cancer Risk, External Hazard Index (Bq/Kg) and

166 167 Internal Hazard Index (Bq/Kg); Equation 1 to 9 was used and the results are presented in the

168 table below.

Table 2 169 **Evaluated Results for Radiation Hazard Indices**

210 3.3 Discussion

187

According to Table 2 and Fig 2, all the locations have their Radium Equivalent Activity values ranged from 100.39-197.40 Bq/Kg with a mean value of 161.44 Bq/Kg. This mean value obtained is lower than the world average of 370 Bq/Kg as reported by regulatory bodies.

214 According to Table 2, the gamma absorbed dose rates calculated using the gamma spectrometry

results ranged from 44.85 - 90.71 nGy/hr with the mean of 73.68 nGy/hr. The mean value

obtained is below the world average of 89 nGy/hr for soil. Even though Figure 3 has obviously

showed that the values for some of the areas like "NW2 C and NW3 C" were higher than the

218 world average of 89 nGy/hr for soil as reported by regulatory bodies.

219 According to Table 2, Annual Gonadal Equivalent Dose (AGED) obtained ranged from

220 315.77mSv/yr to 640.91mSv/yr with the mean of 519.19. The mean value of AGED for the

221 locations is above the threshold value of 300 mSv/yr.

Figure 4 compares the AGED values for the locations with the standard. The high values of AGED for all the locations indicate that the possibilities of developing bone marrow problems, sterility or even leukemia in the long run are high.

According to Table 2, Activity Concentration Index (ACI) calculated for the locations
ranged from 0.73 to 1.45 with the mean value of 1.18 which is above the standard of unity.
Even though figure 4 have obviously showed that the values for some of the areas like "NW2 A

and NW2 B" are lower than the world average.

The Annual Effective Dose Equivalent (for outdoor) was also calculated for the locations and shown in Table 2. The AEDE (outdoor) value ranges between 0.055 to 0.111 mSv/yr with the mean of 0.090 mSv/yr which is above the 0.07 mSv/yr standard permissible limit. The reason might be attributed to high absorbed dose rate values due to high radionuclides concentration in those areas. Even though figure 6 have obviously showed that the values for some of the areas like "NW2 A and NW2 B" are lower than the world average.

On the other hand, the AEDE (indoor) value ranged from 0.220 to 0.445 mSv/yr, with the mean value of 0.361 mSv/yr. The mean value obtained is below the 0.45 mSv/yr threshold. All the locations are below the AEDE (Outdoor) threshold.

238 Excess Lifetime Cancer Risk Index (ELCR) obtained ranged from 00.770 to 1.558 with the mean

value of 1.265 and from 0.193 to 0.389 with the mean value of 0.317 for outdoor and indoor respectively. These values exceed the 0.29 X 10^{-3} threshold limit. All the locations have ELCR

values above the permissible threshold.

External and Internal Hazard indices are below the unity threshold for all the locations (as shown in Table 2 and Figures 10 and 11), with the ranges from 0.271 to 0.533 and 0.289 to 0.675 as well as mean values of 0.435 and 0.512 respectively.

The results showed trends that are generally high for most radiation hazard indices calculated except for few indices whose values are below the recommended thresholds.

Therefore, there may be serious immediate radiological effects to the populace and the environment in these areas except for few locations where the risk due to radiation is less significant even though, all the locations may need further investigation and monitoring.

250 4.2 Conclusion

Soil samples from some selected mining sites in Nasarawa West have been analyzed using the Thallium Drifted Sodium Iodide Gamma Spectroscopy. The activity concentrations of 232 Th,

 226 Raand 40 K obtained were used to determine the radiation hazards indices.

The hazard indices calculated revealed that, the radium equivalent activity is high for all the areas under investigation. AGED values are above the permissible threshold for all the locations. The GADR for all the samples under investigation are lower than the recommended standard except for two locations which are NW2 C and NW3 C. Two of the radiation hazard indices; ACI and AEDE (outdoor) are high for all except two locations, which are, NW2 A and NW2 B. The annual effective dose (indoor) is low for all locations. The ELCR values for both outdoor

and indoor are above 0.29×10^{-3} as reported by regulatory bodies' standard. The remaining two

hazard indices; Hex and H_{in} are below the permissible standards of 1.0Bq/kg for all the locations.

262

Comment [06]: However, it was obviously showed that the values for some of the areas like "NW2 C and NW3 C" were higher than the world average of 89 nGy/hr for soil as reported by regulatory bodies. (Fig 3).

Comment [O7]: For future sake: HpGe may be used

263 4.3 Recommendation

- In the course of this radiometric study, it was discovered that some places are subjected to high radiation hazard indices. These areas will strongly require regulatory control. The level of radiation in those areas is sufficiently high and can cause radiological hazard to the public of the area.
- 267 alea.
- Further investigation is recommended using the High Purity Germanium (HPGe) detector for the
 locations.
