

**Effect of post emergence herbicides on weed management in transplanted kharif rice (*Oryza sativa* L.) and their residuality on soil microorganisms**

**Abstract**

The field experiments were conducted at Regional Research Sub-Station (RRS) of Bidhan Chandra Krishi Viswavidyalaya, Chakdaha, Nadia during 2017-2018. Ten (10) treatments were used following Randomize Block Design (RBD) with three replications and total no of plots was thirty (30). The treatments were T<sub>1</sub>: POE 2, 4-D EE 80 EC @ 425 g ha<sup>-1</sup>, T<sub>2</sub>: POE 2, 4-D EE 80 EC @ 850 g ha<sup>-1</sup>, T<sub>3</sub>: POE 2, 4-D EE 80 EC @ 1280 g ha<sup>-1</sup>, T<sub>4</sub>: POE 2, 4-D EE 80 EC @ 1700 g ha<sup>-1</sup>, T<sub>5</sub>: POE 2,4-D EE 80 EC @ 3400 g ha<sup>-1</sup>, T<sub>6</sub> : EPOE Butachlor 50 EC @ 1000 g ha<sup>-1</sup> at 15 DAT, T<sub>7</sub>: EPOE Bispyribac sodium 10 SC @ 25 g ha<sup>-1</sup> at 15 DAT, T<sub>8</sub>: EPOE Almix 20 WP @ 4.0 g ha<sup>-1</sup>, T<sub>9</sub> : Hand weeding twice 20 and 40 DAT and T<sub>10</sub>: Weedy check . Almix 20 WP @ 4 g ha<sup>-1</sup> applied at 15 DAT as EPOE effectively controlled all categories of weeds resulted minimum weed population, biomass production of weeds and higher weed control efficiency among the chemical herbicides which ultimately produced higher grain yield (3.23 t ha<sup>-1</sup>).

**Key words:** Transplanted *Kharif*rice, herbicides, yield, microbial population

**1.INTRODUCTION**

Rice occupies a pivotal place in Indian agriculture and it is the staple food for more than 70% of population and a source of livelihood for about 120-150 million rural households. It contributes about 43% of total food grain production and 46% of total cereal production in the country [1]. India needs to produce 120 mt of rice by 2030 to feed its one and a half billion plus population [2]. There is no scope for horizontal expansion of cultivable area. Therefore, rice productivity and production have to be increased to meet the future demand. Weed is considered as a major pest and constraint to increase the production of rice [3]. In India, weed control takes 30-35 % share of total cost of crop production and the average yield loss is caused to the tune of 41.2 % [4]. In West Bengal under new alluvial zone the biological yield loss of rice due to weed was 37.02 % and 23.12 % in grain and straw, respectively [5]. This illustrates the importance of weed control in minimizing the yield losses and boosting up the crop productivity. Management of weeds at farm levels is still largely restricted to mechanical and cultural methods [6]. Proper management of weeds, in time, to reduce the crop-weed competition is not possible due to sharp increase in the wage and unavailability of labour due to industrialization and urbanization. In view of this, chemical weed control is becoming more popular throughout the world. Major competition with weeds in rice field occurs during initial 15-30 days after seeding or

germination in direct seeded rice and 30-60 days in transplanted rice [7]. It calls for a detailed study on weed flora in different paddy cultures (transplanted as well as direct seeded paddy) keeping an eye to develop an efficient eco-safe weed management practice for rice cultivation to replace those indigenous method of weed control through the use of effective, economic, socially and environmentally safe chemicals at proper dose, proper time and method of application.

## **2. MATERIALS AND METHODS**

### **2.1 Experimental site**

A field experiment was conducted during 2017 and 2018 at Regional Research Sub-Station (RRS) of Bidhan Chandra Krishi Viswavidyalaya, Chakdaha, West Bengal India in transplanted rice (var- IET 4786). Soil was sandy clay loam type containing (46.50% sand, 25.0% silt and 28.5% clay) with a pH of 6.5. It contained 0.68% organic C, 215.2 kg available N ha<sup>-1</sup>, 25.2 kg available P<sub>2</sub>O<sub>5</sub> ha<sup>-1</sup> and 142.4 kg available K<sub>2</sub>O ha<sup>-1</sup>. The climate of the study site was sub-tropical. Weekly maximum and minimum temperatures ranged between 31.3 to 36.7°C and 14.8 and 27.6 °C during 2017 and 2018 respectively. Maximum relative humidity ranged from 89% to 91.8% in 2017 and 89.2% to 93% in 2018 respectively. The annual rainfall during the experimental period was 1250.0 and 1400.5 mm in 2017 and 2018, respectively.

### **2.2 Herbicidal treatments**

The experiment was laid out in randomized block design and replicated thrice and the area of each plot was 20 m<sup>2</sup> (5.0 m x 4.0 m) with an inter- row spacing of 20 cm. The treatments are consisted of 2, 4-D ethyl ester (80 EC) at five different dosages (425, 850, 1280, 1700 and 3400 g ha<sup>-1</sup>), Butachlor (50 EC) @ 1000 g/ ha, Bispyribac sodium (10 SC) @ 25 g/ha and Almix (20 WP) @ 4 g/ha along with weedy check and weed free check. The amount of the herbicides was calculated as per treatments on the basis of gross plot area and were broadcasted uniformly in the experimental plots as per treatments. 2, 4-D EE was applied 25 DAT and others was applied 15 DAT with their different doses.

### **2.3 Crop management practices**

Healthy paddy seeds (cv. IET 4786) soaked for 24 hours in clean water for better germination. The seeds were treated with *Trichoderma viride* @ 4 g kg<sup>-1</sup> and shade drying for 6 hours prior to sowing. Well germinated seeds were sown on 27<sup>th</sup> and 29<sup>th</sup> June in 2017 and 2018. Twenty two days old seedlings were transplanted @ 3 seedling hill<sup>-1</sup> at a spacing of 20cm x 15cm in both the years. All other cultural and plant-protection measures were also adopted as recommended for the region (Banerjee and Pal, 2009). The individual plot size was 5m × 4m. One-fourth (¼<sup>th</sup>) N along with full P<sub>2</sub>O<sub>5</sub> and ¾<sup>th</sup> K<sub>2</sub>O of RDF were applied as basal (during final land preparation). Remaining ½ N was top-dressed at tillering stage, while ¼<sup>th</sup> each of N and K<sub>2</sub>O was given at panicle initiation stage. Organic manures were applied 7 days before transplanting just to substitute a part of recommended dose of N. However, eco-safe protection measures were taken against yellow stem borer and rice bug.

The crops were harvested manually with sickle at a height of 25-30 cm from ground level on 5<sup>th</sup> and 9<sup>th</sup> October in 2017 and 2018, respectively, then grain yield after threshing and cleaning was recorded from unit plot area and converted into t ha<sup>-1</sup> at 15% moisture content.

## 2.4 Observations on weeds

For weed count and weed biomass, required number of permanent quadrates (0.5 m x 0.5 m) were earmarked in each plot after rice sowing. For taking weed biomass, the destructed weed samples were first washed in clean tap water, then sun-dried and hot-air oven-dried at 70°C for 48 h, and weighed. Weed control efficiency (WCE) was worked out using following equations [8], [9] respectively:

$$WCE = \frac{WDM_c - WDM_t}{WDM_c} \times 100$$

Where, WDM<sub>c</sub> is the weed dry matter weight (g m<sup>-2</sup>) in control plot; WDM<sub>t</sub> is the weed dry matter weight (g m<sup>-2</sup>) in treated plot.

## 2.5 Microbiological observations

The enumeration of the microbial population was carried out on agar plates containing appropriate media following serial dilution technique and pour plate method[10].

## 2.6 Statistical analysis

All the collected data was subjected to analysis of variance (ANOVA) according to the techniques define for simple randomized complete block design (RCBD) as described by Gomez and Gomez [11].

# 3. RESULT AND DISCUSSION

## 3.1 Weed population, weed dry weight and weed control efficiency

The experimental plots were infested with mixed weed flora where broadleaved weeds (BLW) were the most dominating followed by grassy weeds and sedges, irrespective of the dates of observations. Experimental results revealed that least weed population and weed biomass in terms of grasses, sedges and broadleaf weeds were registered under weed free check whereas maximum weed population was recorded under weedy check (Table 1 & 2). Among the tested herbicides the treatment plot received Almix 20 WP (4 kg ha<sup>-1</sup>) resulted lowest weed population (17.1 and 19.0 m<sup>-2</sup> respectively for 30 DAT and 45 DAT) and weed biomass (5.57 and 9.20 g m<sup>-2</sup> respectively for 30 DAT and 45 DAT) throughout the growing period. The weed control efficiency also exhibited similar variations showing the superiority of Almix 20 WP by exerting 57.89 % and 57.97 % higher WCE at 30 and 45 DAT over control treatment, respectively. Unlike other three herbicides used in this experiment, Almix, a sulfonyl urea group herbicide, can able to control all categories of weeds as it is a mixture of Metsulfuron methyl (able to kill the dicot broadleaf weeds) and Chlorimuron ethyl (able to inhibit the

monocot grassy weeds) by blocking the normal function of enzyme ALS/AHAS which is essential in amino acid (protein) synthesis. Without proteins, plants starve to death. These results were also in conformity with the findings of [12] and [13].

### 3.2 Growth and yield attributes

Hand weeding (T<sub>9</sub>) recorded the maximum growth and yield attributing characters exhibiting because of its' capacity to control the broad spectrum of weed (grass + sedge + broadleaf) and thus reduce the competition for resources to the crop with the weeds. Among the herbicidal treatments, the pooled data of two years showed that Almix 20 WP @ 4 g ha<sup>-1</sup> applied as EPOE was recorded the maximum growth and yield attributing characters exhibiting 19.0 % more plant height at 65 DAT; 12.1 % higher LAI at 60 DAT; 8.3 % higher number of panicle m<sup>-2</sup>, 15.8 % panicle weight, 24.0 % more panicle length, 30.2 % higher percent filled grains panicle<sup>-1</sup> and 23.4% higher harvest index over unweeded control (Table 3). This better result of Almix may because of its capability to improve the crop growth by suppressing all categories of weeds as a result of which the crop paddy received minimum competition from weed and utilize the resources maximum. Similar kind of results reported by [14] and [15].

### 3.3 Grain and straw yield

In Lieu Of weed free check, Significant ( $p \leq 0.05$ ) higher yield were exhibited from all the herbicide application treatments as compared to non-treated control. Differential herbicide management had resulted significant grain yield variation of rice cv. Satabdi ranging from 2.91 to 3.23 t ha<sup>-1</sup>. Among the herbicidal treatments, the pooled data of two years showed that Almix 20 WP @ 4 g ha<sup>-1</sup> applied at 15 DAT as EPOE was recorded maximum grain and straw yield which were 59.1 % and 132.7 % higher than unweeded control, respectively (Table 3) but the treatments are statistically dissimilar with each other's. The highest harvest index (41.81%) was obtained from T<sub>8</sub> treated plot, which was statistically at par with all treatments excepting control (33.88%). In case of Almix the higher yield over the other herbicide treatments were recorded and this may be due to the higher growth and yield parameters which is the resultant effects of the inhibition of all weed flora by blocking the normal function of enzyme ALS/AHA. Similar kind of view was expressed by [15] and [16]. Advantages of herbicide application and judicious weed management strategies in improving yield attributes and yield of several crops are supported also by various other research reports [17].

### 3.4 Soil microbial population

The impact of application of different herbicide on total bacteria (*Pseudomonas fluorescense*), total fungi (*Trichoderma viridae*, *Trichoderma harzianum*) and Actinomycetes were recorded during harvesting of rice (Table 4). Different weed management treatments significantly ( $p \leq 0.05$ ) influence

the soil microbial populations. Bacterial population sharply hampered by the application of 2, 4-D ethyl ester ( $3.4 \text{ kg ha}^{-1}$ ) in compared to herbicide free plot *i.e.* weedy check and weed free check. However, lowest fungal and actinomycetes population were depicted from the treatment treated with bispyribac-sodium 10% SC. Almix 20 WP showed satisfied result in case of soil microbial population. The population of soil micro flora was increased with lowering doses of herbicides and ultimately weed free check and weedy check resulted significantly greater microbial population respectively. It is also obtained in the findings of [18], who have reported that there was no longer harmful effects of herbicides generally on soil microbial population except in case of higher concentrations beyond recommended doses. This is might be due to the fact that microorganisms are able to degrade herbicides and utilize them as a source of biogenic elements for their own physiological processes [19]. At harvest the soil microflora population was higher than that observed in prior two observations in all four herbicides used in these two experiments. [20] also expressed similar views.

#### 4. CONCLUSION

From this experiment, it can be concluded that although hand weeding twice at 20 and 40 DAT effectively control all categories of weeds and recorded maximum grain yield ( $3.25 \text{ t ha}^{-1}$ ), it was statistically at par with the Almix 20% WP ( $T_8$ ) treatment which was an effective treatment in respect of all types of weed population, biomass production and weed control efficiency throughout the observation period and resulted in about 59.1 % yield increment of rice over control without showing any phytotoxicity on plants. Based on overall performance, we could be suggested that the application of Almix 20% WP @  $4 \text{ g a.i. ha}^{-1}$  exploit not only better weed management but also improves the yield of rice. Further research is needed to evaluate the carry over effect of herbicides towards next cropping window, and develop timing strategies with minimum effective dosages which could be most economic and ecologically desirable weed management approach for rice based cropping system in eastern India.
