

Services Sector FDI-Growth Nexus in Nigeria: Does Liberalization Policy Matters?

Abstract

Since it is the need of developing countries to step up own industrialization process and growth, and calls for more technology spill-over through foreign investments. This made it a necessity that efforts are made by these countries to attract foreign direct investment (FDI) because of its acknowledged advantages as a tool of economic development. Nigeria in particular joined the rest of the world in the quest for increased FDI inflows arising from the notion that FDI leads to economic benefits within the host country. This study analyzed the role of liberalization policy on the nexus between services sector FDI and economic growth in Nigeria under scenarios with and without structural break for the period 1981-2018. Time series properties were examined using both conventional and unit root tests with structural breaks to account for shift dummy in the series. Their results indicates that the series are stationary at I(1) and this prompt the use of vector error correction model (VECM). The statistical results show existence of long-run relationship between services FDI and economic growth though services FDI spurs growth when policy shift is not included but retards growth when it is included. In the short-run, the estimate under scenario without break reveals significant positive relationship with growth but negative and statistically insignificant under the scenario with break. The overall analyses show that services FDI could only play significant role on Nigeria's growth when there is no change in government policy or intervention. Based on these findings, the policy implications include expansion of more service oriented firms in order to increase sectoral share in the total GDP. The potential benefits from such expansion include creation of jobs, more inclusive growth and development, and the higher plant survival has tendency to increase social prosperity.

Keywords: Services sector, FDI, Net inflows, Economic growth and Nigeria.

1. Introduction

The potential and significant roles of foreign direct investment (FDI) in any developing economy cannot be undermined. FDI encourages an open business climate, builds technologies and advances employee training, and also help towards improving government revenue generation. FDI has been used by most of the developing countries as a substitute in the development finance process and as a key instrument to promote the growth of any economy (Global Development Finance, 2005; Adams, 2009a&b). The term FDI is defined as an investment that is made to acquire a lasting interest in an enterprise operating in an economy other than that of the investor (IMF, 1977). In another dimension, Ogunkola and Jerome (2006) defined it as investments in businesses of another country. This may be in form of greenfield investment or merger and acquisition that involves acquisition of existing assets rather than new investment. It occurs when an investor based in one country (the home country) creates or acquires the ownership of assets in another country (the host country) with the intent to manage that asset. Such investment could be through financial collaborations, joint ventures and technical collaborations, capital markets via Euro issues and through

private placements or preferential allotments (IMF, 1977). Effective operations of FDI are contingent on economic policies of the government, transparency and well supportive infrastructure availability in the host country (Dunning, 1994).

In the literature, there have been a lot of arguments on the relationship between FDI and economic growth. Some studies showed that FDI inflows induces economic growth (Saleen, 2013; Javaid, 2016; Sunde, 2017; Jibir & Abdu, 2017; among others). Some studies report existence of linear and non-linear relationship between FDI and growth (Oladele, 2015; Adekunle & Sulaimon, 2018). However, several other studies advocate that significant positive impact of FDI on growth of host country is contingent on certain factors such as human capital, the availability of quality infrastructures, market size and trade openness, good governance and economic freedom (Adeleke, 2014; Ajide & Eregha, 2015; and Kaliappan, Khamis & Ismail, 2015).

Despite numerous studies that have examined the relationship between FDI (aggregate and sectoral) and economic growth, only few studies exist on the link between services sector FDI and growth (Sen, 2011; Sirari & Bohra, 2011; Saleena, 2013; Sumathy & Sridhar, 2014). These studies were conducted for India. Studies that examined FDI impact on different sectors (primary, manufacturing, and services sectors), Chughtai (2014) conducted for Pakistan while Alfaro (2003) for cross-country although, Cheah (2013) and Kaliappan, Khamis and Ismail (2015) focused specifically on services sector. However, in Nigeria, the existing studies (Ezeanyeji & Ifebi, 2016) focused only on telecommunication services sub-sector while Imoughele and Ismaila (2014) focused on various sectors such as quarrying, telecommunication, building and construction, trading and business and agricultural sectors.

The motivation for this present study is in two folds. First, given the unresolved nature of relationships between FDI (both aggregate and sectoral) and growth, the significance role of liberalization policy was therefore conceived on this relationship. In Nigeria, the major liberalization policy that concerns all sectors including services sector was in 1986 during structural adjustment programme (SAP). In the literature, despite large number of studies that have examined the relationships between FDI and growth, none of these studies ever looked into this dimension. The motive is to see whether liberalization policy could promote services sector FDI and growth relationship in Nigeria. Second, this study employed VEC model through which structural break was introduced. This made the analysis to be partitioned under two scenarios (without and with break). The first scenario gives no consideration to liberalization policy while the second scenario considered it.

The main objective of this study is to explore the significant role of liberalization policy on the nexus between services sector FDI and economic growth in Nigeria. Forecast error variance decomposition in addition was used to measure the degree of variability each variable contributes to the others while granger causality test was used to examine the causal relationship between variables. The Subsequent to introductory section, the remaining part of the paper is structured as follows: Trend analyses of both aggregate and disaggregated services sector GDP and net inflows of services sector FDI (% of GDP) are analysed in section two. Section three discusses the review of the literature. Section four presents the

theoretical framework and methodology adopted for the study. The empirical results are discussed in section five while section six provides conclusion and recommendations.

2. Stylized Facts on Aggregate/Disaggregated Services Sector GDP and Net Inflows of Service Sector FDI (percentage of GDP) in Nigeria

Service sector comprises the following sub-sectors: transport; information and communication; utilities; accommodation and food services; finance and insurance; real estate; professional, scientific and technical services; administrative and support services business services; public administration; education; human health and social services; arts, entertainment and recreation; and other services. This section discusses the trends of aggregate/disaggregated service sector GDP as well as net inflows (measured by % of GDP) in Nigeria. Over a period 1981-2016, aggregate service sector GDP recorded an increasing trend with an average of ₦9828.54. Figure 1, for instance, shows that aggregate service sector GDP stood at ₦3,668.44 million in 1981 and increased to ₦3,892.22 million in 1986, accounted for about 6.1% increase. In 1991, it increased steadily to ₦4,761.09 million and continued till 2006 with an average of ₦7,048.07 million. The same scenario was recorded between 2007 and 2016. During these periods, it marked a magnificent increase, recording an average of ₦20,148.71 million which is higher relative to previous periods.

Figure1: Trend of Aggregate Service Sector GDP in Nigeria

Trends of Disaggregated Service Sector GDP in Nigeria

Table 1 demonstrates the trend of disaggregated service sector GDP in Nigeria. Across the various sub-sectors of services, there were significant variations in their contributions. For instance, between 1981 and 2005, real estate performed higher than other sub-sectors, accounted for about 26.3% of the total GDP. This was followed by public administration with about 19.9% contribution. With liberalization of telecommunication sector, this development stimulates the contribution of information and communication and far above others, recorded

about 28.5% of the total GDP during the period 2006-2018. This was followed by real estates with 20.76%. The sudden increase in the performance of information and communication during this period could be attributed to higher usage of telecommunications and information services and the inflow of FDI in the telecommunications industry.

Net Inflows of Service Sector FDI (% of GDP) in Nigeria

Figure 2 shows that the trend of services sector FDI net inflows (% of GDP) in Nigeria experience fluctuations over the period of 1981 to 2018. Net inflows of services sector FDI (% of GDP) stood at 0.42% in 1981 and increased to 3.6% in 1992. Also, between 1993 and 1999, it recorded tremendous increase. From 2000, however, significant declined was recorded. Such decrease was maintained till 2018 when its contribution is below 0.1%.

3. Literature Review

Several studies had been undertaken on the role of FDI on economic growth. This section provides a brief review of the various empirical findings and conclusions of some existing studies on the subject matter. For country specific studies that focused on developed countries, Akulava and Vakhitova (2010) found that firms with foreign capital perform better than domestic firms across the three sectors of the economy concerning the direct effect of FDI. The results also hold after adding spillovers controls. While analyzing bi-directional relationships between FDI inflows and employment in manufacturing and services sectors in Singapore between 1997 and 2005, Wong and Tang (2011) found evidence of long-run causality, running from employment in manufacturing and services to FDI inflows, and from FDI inflows and services employment to manufacturing employment. Furthermore, there is evidence of short-run causality showing strong FDI-employment and employment linkages, predominantly from the manufacturing to services.

Cross-country evidences on the role of FDI (either total or sectoral) on growth are mixed. A handful studies show significant positive impact while some other studies found significant negative impact. Alfaro (2003), for instance, explored the effect of FDI on growth across sectors (primary, manufacturing, and services sectors) for 47 countries between the periods 1981- 1991. The findings showed a negative relationship between the GDP (primary sector) and FDI inflows, whereas FDI inflows in the manufacturing sector have a positive impact while evidence from the foreign investments in the service sector is ambiguous. While investigated the impact of FDI on economic development of post Comecon transition countries between 1998 and 2009, Melnyk, Kubatko and Pysarenko (2014) found a positive relationship between FDI in former Comecon transitional and developing economies and economic growth. Kaliappan, Khamis and Ismail (2015) examined whether ASEAN countries would be able to attract the services-based FDI and get benefits from the inflows over the period 2000-2010. The findings show that services FDI is positively and significantly determined by human capital, the availability of quality infrastructures, market

size and trade openness, whereas inflation (proxy for macroeconomic stability) is found to be negative and insignificant. In another dimension, Cheah (2013) investigated if FDI could significantly affect export sophistication over the period 2002-2011. The result reveals that FDI per capita has a significant long-term non-linear impact on service export sophistication. In Sub-Sahara Africa (SSA), similar results were found though the emphasis was on total FDI. For instance, Adeleke (2014) employed a combination of Pooled OLS, fixed effects (FE) and random effects (RE) techniques to examine the interaction of FDI and governance on growth across 31 SSA countries for the period 1996-2010. The result reveals that FDI significantly promote growth, especially when it is accompanied by good governance. Also, in a panel analysis that involves 19 SSA countries during the period 1995-2010, Ajide and Eregha (2015) found a positive relationship between FDI inflows and GDP per capita in the region when economic freedom is controlled for.

With respect to country specific studies that focus on developing countries, evidence has shown that aggregate or sectoral FDI significantly stimulates growth. For instance, Sen (2011) adopted OLS technique and found that during the period 1970-2008, phenomenal growth of the services sector in India is mainly influenced by trade, hotels and restaurants, transport, storage and communications sector. Using descriptive approach, Sirari and Bohra (2011) also found that over the period 1991-2010, FDI has helped to raise output, productivity and employment at the sectoral level of Indian economy, especially in service sector. With FDI in India, studies such as Saleena (2013) and Sumathy and Sridhar (2014) all found existence of a positive relationship between FDI inflow and growth of service Sector. For emerging countries, Almfraji and Almsafir (2013) employed ECM approach to examine FDI-EG relationship in Malaysia and found significant positive, but negative or even null in some cases. During the period 1986-2016, Saleh *et al.* (2017) found that service sector FDI in Vietnam are driven by market-seeking, government policies and culture, all of which have significantly contributed to FDI. Similar findings are reported in most of the developing countries. For instance, Javaid (2016), with the use of ARDL found existence of a positive and significant impact of FDI on economic growth of Pakistan. Using the same approach, Sunde (2017) found that both FDI and exports boosts economic growth of South Africa.

Specifically, in Nigeria, a handful studies have found mixed results with regards to the relationship between FDI (either total or sectoral) and growth are mixed. For instance, Ezeanyeji and Ifebi (2016) used OLS technique and found a positive and significant impact of FDI on the performance of the telecommunication sector provided there exists a stable political environment. In a related study that focused on sectoral classification and sub-sector, Imoughele and Ismaila (2014) found that constant inflow of FDI across sectors in Nigeria has tendency to stimulate its growth rate. Using VECM, Jibir and Abdu (2017) found positive and significant link between FDI and growth in Nigeria, though non-existence of causality in their relationship. However, in an attempt to examine the sectorial inflow of FDI on Nigeria's economic growth over a period 1970-1998, Oladele (2015) with the use of OLS found that due to inconsistency of Nigeria government policy and framework, significant positive impact exists only in the short-run whereas negative impact in the long-run. Correspondingly, Adekunle and Sulaimon (2018) employed ARDL approach to analyze the relationship

between foreign capital flows and economic growth in Nigeria. Their results also reveal a significant positive impact of net FDI on growth.

4. Theoretical Framework

The theoretical framework for this study follows Romer (1990), Grossman and Helpman (1991), and Barro and Salai-martin (1995). These scholars assumed that capital deepening in the form of increasing the numbers of varieties of capital goods in an economy strictly depend on the available technical progress. Given this condition, the link between services sector FDI and the growth of Nigerian economy can be analyzed using augmented Cobb-Douglas production function as follows.

$$Y_t = AH_t^\alpha K_t^{1-\alpha} \quad (1)$$

Where, Y_t is real output at time t, H_t represents human capital and K_t denotes physical capital at time t. It should be recognized that spillover effect could be generated through the existence of additional stock of services FDI. The spillover effect is otherwise known as externality and it is expressed as:

$$E_t^\gamma = [H_t, K_t]^\delta \quad (2)$$

By incorporating the component of externality into the production function, equation (1) can be rewritten as:

$$Y_t = AH_t^\alpha K_t^{1-\alpha} E_t^\gamma \quad (3)$$

Where; A captures the production efficiency, while α and $1-\alpha$ are the shares of labour and capital inputs.

Substituting equation (2) into (3); we have;

$$Y_t = AH_t^{\alpha+\delta} K_t^{(1-\alpha)+\delta} \quad (4)$$

From equation (4), dynamic production function can be generated by taking both its logarithms and time derivatives and thus becomes;

$$g_y = g_A + (\alpha + \delta)g_t + (1 - \alpha - \delta)g_t \quad (5)$$

Where g_t is the growth rate of Y_t , A_t , H_t and K_t , respectively.

Equation 5 shows that growth of an economy is contingent on increasing FDI associated factors such as efficient production techniques¹; human capital development; technology transfer and capital deepening which have important effects in spurring economic growth. These growth-spurring factors are considered essential to stimulate growth through FDI both at aggregate and sectoral levels.

¹ Act of upgrading already existing products and services together with designing new ones.

4.1 Methodology

The study begins with examination of time series properties in order to ensure consistent estimation of the relationships among the series. Based on the outcome of the time series examined, this study employs vector error correction (VEC) model which is a special case of the VAR, mostly used when variables are stationary in their differences (i.e., I(1)). The VEC can also take into account any cointegrating relationships among the variables. Since the series are found to exhibit at least one-cointegrating equation, it is therefore required to estimate a vector error correction (VEC) model with the incorporation of an error correction mechanism term from the estimated VAR model. The model for this study is specified as:

$$\Delta V_t = \delta_{it} + \sum_{i=1}^k \beta_{ij} \Delta V_{t-j} + \phi_{ij} ECM_{t-j} + \varepsilon_{it} \quad (6)$$

Where;

V_t = vector of variables [RGDP, SFDI, OPT, CPI, EXR, SERLIB, GFCFGDP, SEREM].

V_{t-j} = Vector of lagged variables

δ_{it} = vector of intercept.

ε_{it} = error term

Note: all the variables are in logged form except CPI

4.2 Estimation Technique and Procedures

The estimation procedures begin with the examination of the stochastic properties of the data in which unit root tests are performed. The variables used for the analysis are subjected to different unit root tests in order to determine stationary or non-stationary of the series. The motivation behind the variety of tests is to find reliable and consistent results. Apart from the conventional unit root tests of Augmented Dickey Fuller (ADF) and the Phillips-Perron (PP), this study also considers the Kwiatkowski-Phillips-Schmidt-Shin (KPSS). These are all designed to overcome the difficulties of low power and size distortions inherent in the conventional unit root tests (Madalla and Kim, 1998). In addition to the conventional methods, unit root tests with structural breaks (Perron 2006 and Zivot-Andrews (ZA)) were conducted to determine unexpected shift in time series that can lead to unreliable estimates. In each of these tests performed, the null hypothesis with intercept and trend was considered to determine whether each of the variables in the model being analysed is stationary or not. However, in the empirical analysis, structural break was considered only for services FDI to reflect the period of SAP in Nigeria. Based on this, we included a dummy variable (dummy_SFDI) into the model to account for this structure break.

Following was the cointegration test using the vector error correction model (VECM) technique developed by Johansen (1988). In addition, diagnostic tests were performed on the model. Finally variance decomposition analysis and granger causality test were undertaken to determine how much of the forecast error variance for each variable attributable to its innovations and innovations in the other variables in the system. The entire data set covered the period 1981 to 2018 for which data are available.

Table 2: A priori Expectation of the Variables used in the model

| Abbreviation of Variables | Explanation of Variables | Measurement | Expected relationship (sign) | Data source |
|---------------------------|---------------------------------------|--|------------------------------|-------------------------------------|
| RGDP | Real GDP (a proxy of Economic growth) | GDP at market prices (constant 2010 US\$). | | CBN statistical bulletin |
| SFDI | Services sector FDI | FDI inflows into services sector | + | CBN statistical bulletin |
| EXR | Exchange rate | Real exchange rate | - | CBN statistical bulletin |
| OPT | Openness to trade | (Export + Import)/GDP | + | CBN statistical bulletin |
| CPI | Consumer price index | Consumer price index | - | World Development Indicators (WDI) |
| SEREM | Total employment of services sectors | | + | National Bureau of Statistics (NBS) |
| GFCFGDP | Gross fixed capital formation | Gross fixed capital formation | + | CBN statistical bulletin |
| SERLIB | Services sector liberalization | Dummy variable (used the value of 0 to capture period before SAP while the value of 1 for SAP and post-SAP period. | +/- | Author's formulation |

5. Empirical Results and Discussion

5.1 Unit Root Tests

Time series properties of the variables used in the model were tested by performing a univariate regression (i.e. unit root test). To ascertain whether each of these variables has unit root (non-stationary) or does not have unit root (stationary series), this study used three (3) of the conventional unit root tests (ADF, PP and KPSS) and two (2) of the unit root tests with structural breaks (Perron 2006 and Zivot-Andrews tests). An observation from the summary results of the unit root tests presented in Table 3 indicates that all the variables are non-stationary in their levels $I(0)$ but at first difference $I(1)$. Based on this, there is a need to conduct a cointegration test in order to confirm the existence of long-run relationship among the variables in the model.

Table 3: Summary and Decision for Unit Root Tests

| Variables | ADF | PP | KPSS | ZA | Perron 2006 | Decision |
|-----------|------|------|------|------|-------------|----------|
| LRGDP | I(1) | I(1) | I(0) | I(1) | I(0) | I(1) |
| LSFDI | I(1) | I(1) | I(0) | I(1) | I(1) | I(1) |
| LCPI | I(1) | I(1) | I(1) | I(0) | I(0) | I(1) |
| LEXR | I(1) | I(1) | I(1) | I(1) | I(1) | I(1) |
| LGFCF | I(1) | I(1) | I(0) | I(1) | I(0) | I(1) |
| LSEREM | I(1) | I(1) | I(1) | I(1) | I(0) | I(1) |
| OPT | I(1) | I(1) | I(0) | I(1) | I(0) | I(1) |
| LGFCFGDP | I(1) | I(1) | I(1) | I(1) | I(0) | I(1) |

Source: Derived from Table A1 and A2 in the appendix.

Note: The decision made in each of the tests is based on the estimation results with consideration to intercept and trend. I(0) represents stationary of a variable (i.e. significant at level) while I(1) denotes non-stationary (i.e. significant at first difference).

Following the results of the stationary tests, an attempt is made to verify the existence of co-integration among non-stationary variables using Johansen co-integration test. In Table 4, the trace statistic reveals the existence of four co-integrating equations in the model. However, the result from the maximum-eigen statistic reveals the existence of one co-integrating equation in the model. To establish long-run relationship, there must be existence of at least one co-integrating equation in the mode. Given this condition, the null hypothesis of no co-integration is rejected at 5% critical value for both trace and maximum-eigen statistic.

Table 4: Co-integration Test Result

| H_0 | H_1 | Trace statistic | | Max-Eigen statistic | |
|------------|------------|-----------------|-------------------|---------------------|-------------------|
| | | λ Trace | 5% critical value | λ Max | 5% critical value |
| $r=0$ | $r=1$ | 226.7950 | 159.5297 | 73.71110 | 52.36261 |
| $r \leq 1$ | $r \geq 2$ | 153.0839 | 125.6154 | 40.88417 | 46.23142 |
| $r \leq 2$ | $r \geq 3$ | 112.1997 | 95.75366 | 35.33332 | 40.07757 |
| $r \leq 3$ | $r \geq 4$ | 76.86639 | 69.81889 | 31.54408 | 33.87687 |

Note: *** implies significant at 1%, while ** implies significant at 5% and * significant at 10%.

In estimating VECM, the optimal lag length needs to be determined and this is based on five different information criteria which are: Akaike Information Criterion (AIC), Schwartz Information Criterion (SIC), Hannan-Quinn Information Criterion (HQ), Final Prediction Error (FPE) and Sequential Modified LR test Statistic. Thus, Table 5 reveals the optimal lag length suggested for the stochastic equation is one, i.e. $p^*=1$ is chosen.

Table 5: Maximum Lag Length Table

| VAR Lag Order Selection Criteria | | | | | | |
|---|-----------|-----------|-----------|------------|------------|------------|
| Endogenous variables: LRGDP LSFDI OPT LEXR CPI LSEREM SERLIB LGFCFGDP | | | | | | |
| Lag | LogL | LR | FPE | AIC | SC | HQ |
| 0 | -169.4309 | NA | 2.02e-06 | 9.590859 | 9.939166 | 9.713653 |
| 1 | 139.9925 | 468.3165* | 3.79e-12* | -3.675271* | -0.540512* | -2.570122* |

Note: * indicates lag order selected by the criterion.

5.2 Vector Error Correction Model

Table 6 shows the estimates of a VEC model for the co-integrated variables in order to evaluate both the short-run and long-run relationships between the co-integrating variables. For the long-run, causal relationship is determined by the significance of the error correction term. However, short-run causal relationship is established by the sum of the lagged coefficients of the explanatory variables at a given significance level.

The analysis of this study is done under two (2) scenarios. The first scenario is estimated without the consideration of break period while the second scenario is estimated with the inclusion of break for both for both long-run and short-run estimations as presented in Table 6. The rationale for this innovation is to verify whether the incidence of break (i.e. structural or policy shift) tends to overestimate or underestimate the coefficients of the variables in the model. As reveal in Table 6, there exists a long-run relationship between economic growth and services FDI under both scenarios (without and with inclusion of break). This is shown by the coefficient of error correction term (ect(-1)) which is negative, less than zero and statistically significant. The ect(-1) coefficients under the two scenarios (i.e. without and with break) show that unbalance economic growth in the short-run could be adjusted within the first quarter of the year.

In the long-run estimates under scenario without break, RGDP has significant positive relationship with LSFDI, but significant negative relationship with OPT, LEXR, SERLIB and CPI. However, under the scenario with break, RGDP has significant positive relationship with LSEREM while negative relationship with other explanatory variables together with structural breaks (dummy_SFDI). This is an indication that without consideration to the inclusion of policy shift in the model, LSFDI significantly spurs growth but retards it with inclusion of policy shift.

Table 6: Estimates of Vector Error Correction Model

| Variables | Long-run Estimates | |
|-------------------------|------------------------|------------------------|
| | Without break | With break |
| LSFDI(-1) | 0.058 (10.600)*** | -0.112 (-4.872)*** |

Note: *** implies significant at 1%, while ** implies significant at 5% and * significant at 10%.

In the short-run analysis, estimates under the two scenarios reveal that the lag value of RGDP in period one D(LRGDP(-1)) has significant positive relationship with the current RGDP. In the case of LSFDI, the estimate under scenario without break reveals significant positive relationship with growth but negative and statistically insignificant under the scenario with break. This indicates that services sector FDI could only play significant role on Nigeria's growth provided there is no change in government policy or intervention. Inflation rate

proxied by CPI has significant negative relationship with growth under the two scenarios. This conforms to the theoretical expectation. Total employment in the services sector has significant negative relationship with growth under scenario without break and this does not conform to the theoretical expectation. More so, under scenario with break, exchange rate has significant positive relationship with growth. This implies that depreciation of domestic currency promotes growth. However, liberalization of services sector (SERLIB) reveal significant negative relationship with growth and this does not conform to the theoretical expectation. Lastly, structural shift denoted by dummy_SFDDI reveals significant negative relationship with growth. This connotes that such policy shift may not be favourable possibly because of the associated conditionalities and as a result retards growth in Nigeria.

In the diagnostic test results presented in Table 6, there is evidence of no serial correlation. This is shown by the LM statistic of 46.705 and 66.914 with probability of 0.949 and 0.869. This therefore suggests that the null hypothesis of no serial correlation cannot be rejected. The F-statistic shows that the overall fitness of the models are 3.55 and 2.59 at 5% significant level. The results of R-squared are 0.55, and 0.51, respectively. This connotes that in the short-run, changes in RGDP under scenario without break is accounted for by 55% variation in the explanatory variables while accounted for 51% variation in the explanatory variables in the model under scenario with break.

5.3 Forecast Error Variance Decomposition

This measures the proportion of variability each variable contributes to the other variables in the autoregression. It is used to determine how much of the forecast error variance for each variable that is attributable to its innovations and innovations in the other variables in the system. Presented in Table 7a and 7b are the results of the variance decomposition analysis showing the proportion of the forecast error variance in LRGDP explained by its own innovations and innovations in explanatory variables both under the two scenarios (i.e. without break and with break).

Table 7a: Variance Decomposition of LRGDP (without break)

| Period | S.E. | LRGDP | LSFDDI | OPT | LEXR | SERLIB | LGFCFGDP | CPI | LSEREM |
|--------|----------|----------|----------|----------|----------|----------|----------|----------|----------|

Source: Author's computation.

The variance decomposition analysis above covers a period of 10 years so as to ascertain the roles of innovation attributed to other variables in the system on LRGDP for a relatively long time. During the first year, LRGDP is strongly endogenous as it strictly explained by its own innovations, as suggested by Brooks (2002). During this period, innovations from other

variables accounted for 0% of its variation. At period 4, LRGDP is weakly endogenous as it is explained by about 66% of its own innovation while explanatory variables accounted for 34% of the error variance. For instance, LSFDI explains about 10%, OPT accounts for about 6% while innovation attributed to LEXR accounted for about 13%. Also, it is observed that innovation in LEXR is on the increase and ahead of innovation in OPT and LSFDI.

At period 10, LRGDP explains about 40% of its own variation. The remaining 60% is explained by the explanatory variables in the system. During this period, innovation in LEXR substantially increases to about 30% while that of LSFDI increases to about 21% and OPT remains at about 4%. This connotes that larger proportion of about 60% error variance in LRGDP is attributed to innovations in the explanatory variables in the system.

Similarly, in the first year under the scenario with break, LRGDP is strongly endogenous as it strictly explained by its own innovations. Innovations from other variables accounted for 0% of its variation. However, at period 4, LRGDP is strongly endogenous, accounted for about 81% of its own innovation while explanatory variables accounted for 19% of the error variance. During this period, innovations from LSFDI, LEXR, dummy_SFDI and OPT accounted for about 6%, 5%, 4% and 3%, respectively. With inclusion of break in the analysis, it is observed that innovation from policy shift is marginally increasing throughout the period under consideration.

Table 7b: Variance Decomposition of LRGDP (with break)

| Period | S.E. | LRGDP | LSFDI | OPT | LEXR | SERLIB | LGFCFGDP | CPI | LSEREM | dummy_SFDI |
|--------|----------|----------|----------|----------|----------|----------|----------|----------|----------|------------|
| 1 | 0.016453 | 100.0000 | 0.000000 | 0.000000 | 0.000000 | 0.000000 | 0.000000 | 0.000000 | 0.000000 | 0.000000 |
| 2 | 0.029986 | 95.39809 | 0.635165 | 1.519265 | 0.470293 | 0.868489 | 0.042457 | 0.200456 | 0.614787 | 0.250997 |
| 3 | 0.040972 | 89.06330 | 2.795127 | 2.806026 | 0.567976 | 0.465283 | 0.366533 | 0.816537 | 0.475461 | 2.643757 |
| 4 | 0.051419 | 80.49442 | 5.476936 | 2.982095 | 4.629590 | 0.648647 | 0.328916 | 0.673210 | 0.404427 | 4.361763 |
| 5 | 0.060174 | 73.94617 | 7.445481 | 2.423497 | 9.259168 | 0.666809 | 0.264216 | 0.491692 | 0.339394 | 5.163575 |
| 6 | 0.067831 | 69.64583 | 8.533158 | 2.024164 | 12.57412 | 0.779427 | 0.213206 | 0.481304 | 0.310469 | 5.438328 |
| 7 | 0.074441 | 67.15080 | 9.236407 | 1.765851 | 14.27066 | 0.834076 | 0.188522 | 0.602098 | 0.291843 | 5.659739 |
| 8 | 0.080602 | 65.18592 | 9.797028 | 1.597426 | 15.34682 | 0.937811 | 0.189139 | 0.863195 | 0.280309 | 5.802354 |
| 9 | 0.086386 | 63.44660 | 10.29428 | 1.461298 | 16.10421 | 1.042289 | 0.208470 | 1.264623 | 0.271131 | 5.907102 |
| 10 | 0.091932 | 61.78810 | 10.72628 | 1.347112 | 16.67190 | 1.167411 | 0.253372 | 1.820833 | 0.264053 | 5.960942 |

Source: Author's computation.

At period 10 under scenario with break, LRGDP explains about 62% of its own variation. The remaining 38% is explained by the explanatory variables in the system. During this period, innovation in LEXR considerably increases to about 17% while that of LSFDI increases to about 11%, dummy_SFDI accounts for about 6% and OPT remains at 1%. This explains that with inclusion of break, proportion of error variance in LRGDP attributed to innovations in the explanatory variables in the system accounted for about 38%.

Generally, the variance decomposition analysis results under the two scenarios conform to economic theory. This is because shocks to the explanatory variables continued to explain a significant proportion of the variation in RGDP.

5.4 Granger Causality Test

The granger causality test results presented in Table 8 is conducted to examine the role of services sector FDI on economic growth in Nigeria. The result shows that there is a uni-

directional causality between real GDP and SFDI. This implies that the growth of Nigerian economy is significantly influenced by services sector FDI. More so, the result shows the existence of uni-directional causality between RGDP and inflation rate proxied by CPI. This shows that growth of Nigerian economy is significantly influenced by inflation rate. This further confirms the empirical findings that inflation rate is an important factor that inhibits growth. In addition, the result shows uni-directional relationship between RGDP and total employment in the services sector (SEREM). This is also expected because employment generation is an important indicator of growth. Therefore, the higher employment created by services sector, the higher the contribution of the sector to the growth of Nigerian economy. However, between RGDP and OPT, RGDP and EXR, RGDP and SERLIB, RGDP and GFCFGDP, there exists no causal relationships. This is an indication that openness to trade (OPT), exchange rate (EXR), liberalization of services sector (SERLIB), gross fixed capital formation as a percentage of GDP (GFCFGDP) do not have play significant role of the growth of Nigerian economy.

Table 8: VEC Granger Causality

| Null Hypothesis | Chi-square statistic | Probability | Remarks |
|------------------------------------|----------------------|-------------|---------|
| RGDP does not granga cause SFDI | 6.084078 | 0.0136 | Reject |
| SFDI does not granga cause RGDP | 0.586560 | 0.4438 | Accept |
| RGDP does not granga cause OPT | 0.424042 | 0.5149 | Accept |
| OPT does not granga cause RGDP | 0.968430 | 0.3251 | Accept |
| RGDP does not granga cause EXR | 0.112397 | 0.7374 | Accept |
| EXR does not granga cause RGDP | 1.93E-05 | 0.9965 | Accept |
| RGDP does not granga cause SERLIB | 1.310306 | 0.2523 | Accept |
| SERLIB does not granga cause RGDP | 2.117392 | 0.1456 | Accept |
| RGDP does not granga cause GFCFGDP | 0.000205 | 0.9886 | Accept |
| GFCFGDP does not granga cause GDP | 0.128306 | 0.7202 | Accept |
| RGDP does not granga cause CPI | 8.182192 | 0.0042 | Reject |
| CPI does not granga cause RGDP | 0.231145 | 0.6307 | Accept |
| RGDP does not granga cause SEREM | 2.922312 | 0.0874 | Reject |
| SEREM does not granga cause RGDP | 0.246334 | 0.6197 | Accept |

Source: Author's computation.

6. Conclusion and Policy Recommendations

This paper explores the role of liberalization policy on the nexus between Services Sector FDI and economic growth in Nigeria. It utilizes vector error correction model (VECM) to assess both short and long-run relationships. The results show existence of long-run relationship between services FDI and economic growth though services FDI spurs growth

when policy shift is not included but retards growth when it is included. In the short-run, the estimate under scenario without break reveals significant positive relationship with growth but negative and statistically insignificant under the scenario with break. This indicates that services FDI could only play significant role on Nigeria's growth provided there is no change in government policy or intervention. Based on these findings, the policy implications include expansion of more service oriented firms in order to increase sectoral share in the total GDP.

The policy implication is that since most developing economies like Nigeria stands to gain much economic benefits from services FDI when they are open to foreign trade, Nigerian government should intensify efforts towards reducing the bureaucratic bottlenecks in foreign trade transactions which is characterized by stringent custom duties and port-authorities' regulations. Policy makers should formulate policies that will encourage foreign investors. Expansion of more services oriented firms tends to increase the sectoral share of the total GDP. The potential benefits from such expansion include creation of jobs, more inclusive growth and development, and the higher plant survival has tendency to increase social prosperity.

Table A2: Unit Root Tests with Structural Breaks

| Variables/Method | Zivot-Andrews (ZA test, 1992) one-break | | Perron 2006 with one break | |
|------------------|---|-------------|----------------------------|--------------|
| | TB | t-stat | TB | t-stat |
| LRGDP | 1991 | -2.49389 | 2000 | -5.530637*** |
| LSFDI | 2000 | -3.50696 | 1997 | -2.849572 |
| CPI | 1994 | -5.66812*** | 1992 | -5.684262*** |
| LEXR | 1999 | -3.91091 | 1999 | -2.527850 |
| LSEREM | 2002 | -4.50276 | 2000 | -3.996324*** |
| OPT | 2005 | -3.49424 | 2004 | -3.204990* |
| LGFCFGDP | 2007 | -4.12462 | 2006 | -3.394604* |

Source: Computed.

Note: t indicates the t-statistic and TB denotes the structural break dates. The critical values for Perron (2006) are given at the 1%, 5% and 10% significance levels as -3.9759, -3.4185 and -3.1314. The critical values are given at the 1% and 5% significance levels as -5.57 and -5.08 for the Zivot-Andrews one-break unit root test.
